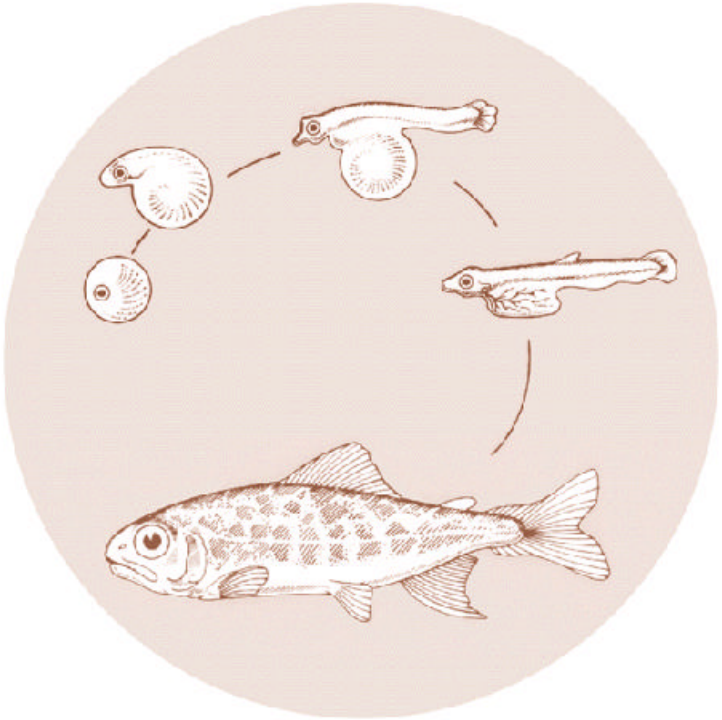
December 1984

EVALUATION OF THE CONTRIBUTION OF CHINOOK SALMON REARED AT COLUMBIA RIVER HATCHERIES TO THE PACIFIC SALMON FISHERIES

Annual Report 1984



DOE/BP-392

This report was funded by the Bonneville Power Administration (BPA), U.S. Department of Energy, as part of BPA's program to protect, mitigate, and enhance fish and wildlife affected by the development and operation of hydroelectric facilities on the Columbia River and its tributaries. The views of this report are the author's and do not necessarily represent the views of BPA.

ABSTRACT

FY 1984 was the sixth year of an eight-year study to determine the distribution, contribution, and value of artificially propagated fall chinook on the Columbia River. Tagging of hatchery fall chinook was completed in FY81. Sampling of sport and commercial marine fisheries from Alaska through California, Columbia River fisheries, and Columbia River hatcheries and adjacent streams occurred in 1984. Catches and returns of three brood years tagged (1979-1981) could have occurred in 1984.

Total returns of fall chinook to Columbia River facilities in 1984 were 74,401. This was the second smallest return over the past five years. Returns to Bonneville, Spring Creek, Little White Salmon, Klickitat and Klaskanine hatcheries were smaller than any previous year during this study. However, returns to Priest Rapids and Sea Resources hatcheries were greater than in previous years.

Final estimated catch values are available through 1982 for British Columbia, Washington, Oregon and Columbia River fisheries. Fall chinook from the Columbia River hatcheries are predominately recovered in these fisheries. The percentages of the 1978-brood fish caught in these fisheries was 40.3, 35.0, 7.5 and 17.2 respectively.

Contributions to the fisheries per 1,000 fish released for all hatcheries combined were 2.6 and 3.0 for the 1978 and 1979 broods respectively. Three years (1980-1982) were included in the contribution values for the 1978 brood and two years (1981 and 1982) for the 1979 brood- Spring Creek Hatchery had the greatest contribution to the fisheries of 8.2 and 12.7 fish per 1,000 fish released for the 1978 and 1979-broods respectively. The Spring Creek contribution was followed by Stayton Pond, Abernathy, Bonneville and Big Creek at 6.3, 4.1, 2.9 and 2.6 respectively for the 1978 brood and Big Creek, Stayton Pond and Abernathy at 7.4, 6.2 and 3.9 respectively for the 1979 brood. Other facilities had contributions per 1,000 releases of less than 2. These contributions are minimums since all possible catch years are not included.

STUDY GOALS AND OBJECTIVES

In 1979 the Bonneville power Administration (BPA) began funding an 8-year study to determine the distribution, contribution, and value of fall chinook salmon raised at Columbia River rearing facilities. Information from this tagging study will provide data to determine the effectiveness of hatcheries constructed as mitigation for hydroelectric developments. In addition, this data will aid fishery agencies in planning further measures to protect, mitigate, and enhance salmon runs on the Columbia River. This information is important to regulating bodies, such as the Pacific Fishery Management Council, charged with negotiating, setting, and adjusting fishing seasons, locations, and limits. Current regulations are based on data from a fin-marking study completed over ten years ago. Since completion of that study, new rearing facilities have been built, existing facilities renovated, alterations in sport and commercial fisheries have occurred, and hatchery practices have changed.

The objectives of the study are to: 1) determine the contribution of hatchery fall chinook from Columbia River hatcheries to individual Pacific salmon fisheries by age class of fish, and 2) determine the distribution, contribution, and value of each hatchery's production of fall chinook to Pacific coast salmon fisheries.

The desired goal to achieve objective 1 was to tag a constant percentage of fish at each rearing facility. A goal of tagging at least 150,000 fish at each facility was set to achieve objective 2. We have attempted to meet both goals at each hatchery. This required additional tag codes at some hatcheries because the number of fish tagged for the constant percentage was insufficient to meet the 150,000 goal. This report briefly describes tagging, release and recovery activities during the first six years of the study and details activities and preliminary results during FY 1984.

STUDY DESCRIPTION

The National Marine Fisheries Service (NMFS) is coordinating the study among three fisheries agencies: U.S. Fish and Wildlife Service (USFWS), Oregon Department of Fish and Wildlife (ODFW), and Washington Department of Fisheries (WDF).

Tagging

From 18 to 20 facilities rearing fall chinook on the Columbia River were included in this study each year (Figure 1). Personnel from the participating agencies tagged a portion of the fall chinook production at most Columbia River facilities rearing fall chinook. The fish at each facility received a distinctive mark consisting of an adipose fin clip and insertion of a unique coded wire tag in the snout. From 2.5 to 5 percent of the production at each facility was randomly selected for tagging. Sampling devices developed by WDF and NMFS were used to select the fish for tagging.

Figure 1. - COLUMBIA RIVER FACILITIES PARTICIPATING IN THE FALL CHINOOK STUDY

ODFW and USFWS personnel used a mobile tagging unit constructed by NMFS with BPA funds to tag fish at their facilities. WDF used their own tagging equipment. During the four brood years, 1978 through 1981, nearly 15 million fall chinook were tagged. The numbers tagged each year were 4,379,300, 3,009,900, 3,660,500, and 3,651,300.

Except for the 1978-brood fall chinook at ODFW and USFWS facilities, tagged fish were returned to the populations of untagged fish from which they came.

Prerelease Sampling

During the tagging operation at each facility, tagging supervisors randomly removed a minimum of 2,000 tagged fish. These fish were held separately and were examined at the time of the facility's production release to determine tag retention at release. Just prior to release, fall chinook populations at most the participating facilities were sampled to determine the tagged to untagged ratios. In many cases these ratios were used to determine the numbers of tagged and untagged fish released.

Releases

Nearly 14 million tagged fall chinook were released from the participating facilities during the four brood years- Releases were 4,035,100, 2,864,700, 3,466,400, and 3,475,500 for the 1978 - through 1981-brood years, respectively. The percentage of the releases tagged each year was 4.4, 3.5, 3.9, and 4.1 for the four broods, respectively. Total releases ranged from 81 million to 92 million from the participating facilities (Tables l-4).

Downstream Migration

Research personnel from NMFS' Northwest and Alaska Fisheries Center sampled the Columbia River estuary and marine waters near the mouth of the Columbia during the migration time of the four broods of fall chinook. The purposes of this sampling were to: 1) define migrational characteristics of marked salmonid stocks from release site through the estuary, 2) provide data to assist in evaluating different hatchery production techniques within a release year, and 3) determine juvenile survival to the estuary for selected stocks and compare this survival with fishery contribution and hatchery returns of these stocks. The usefulness of this sampling for evaluating hatchery techniques and determining potential fishery contribution and survival ranges for fall chinook will not be fully evident until the final catch and return data are compiled.

Sport and Commercial Fishery Recoveries

Sport and commercial fisheries from Alaska through California are being sampled for wire tagged salmonids (Figure 2). Recoveries of the 1978-brood began in 1980. Fishery recoveries of the 1981 brood will not be complete until 1986 (Table 5).

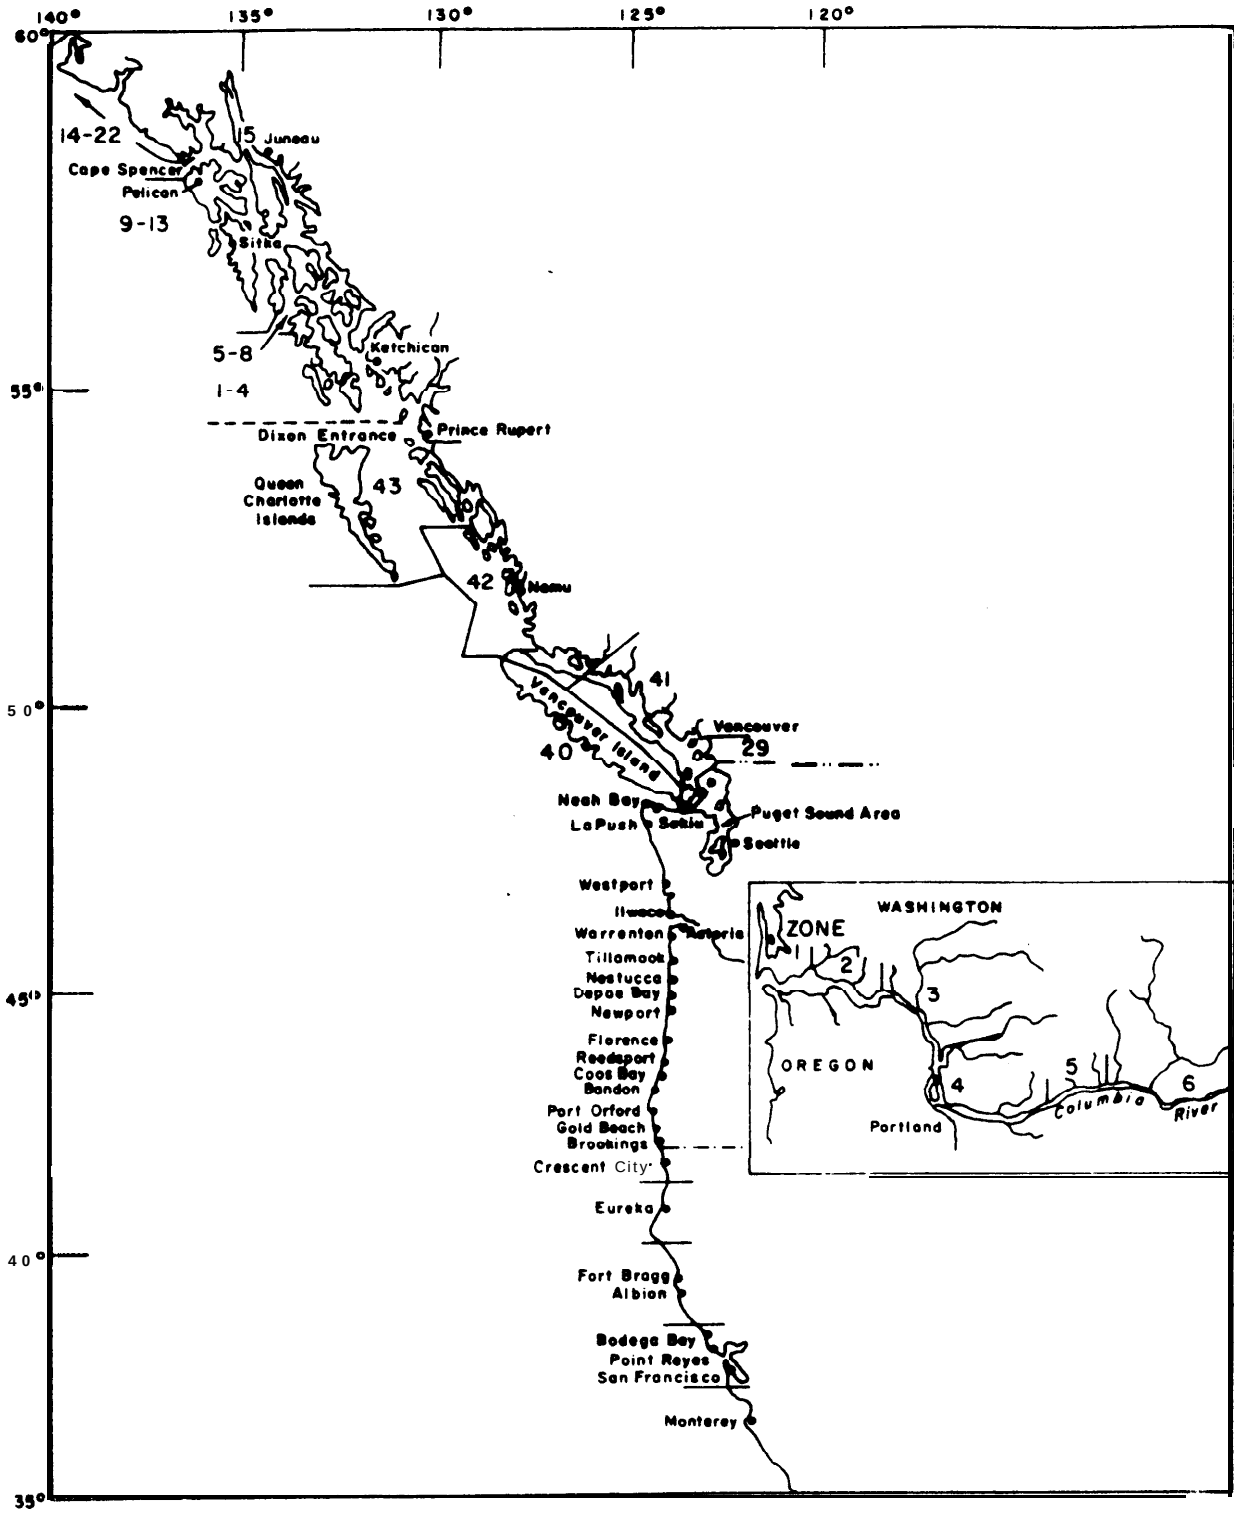

Figure 2. Ports and zones sampled for marked **fall** chinook solmon of Columbia River origin.

Table 5. Recovery years of the 1978– through 1981–brood fall chinook from Columbia River hatcheries.

	Calendar Year						
Brood Year	1980	1981	1982	1983	1984	1985	1986
1978	X	X	X	X			
1979		X	X	X	X		
1980	.		X	X	X	X	
1981				X	X	X	X

Hatchery Returns

Personnel from WDF, ODFW, and USFWS examine all returning fall chinook for the absence of fins. Biological data are collected from untagged returns at a predetermined systematic sampling rate. Samplers remove the snout of all fish with a missing adipose fin. The biological data will be used to estimate the ages of untagged fish. The age structure for tagged and untagged fish will be compared to determine if tagging changes the age distribution of returning adults.

Data Analysis

The factors to be examined at the completion of the study are summarized in Table 6. Analysis of some factors may be limited to simply noting an occurrence. Many of the factors are intertwined (confounded) which may prevent a direct cause and effect relationship. For example, there are no quantitative measures for disease history. It is not possible to make a comparison between groups of fish where group A is known to be X percent healthier than group B. The best that can be done is to note group A had such and such diseases and group B had none. Thus the diseases in group A would be a likely reason for lower survival (assuming there was lower survival). However, the confounding of the factors of disease, rearing environment, time and size of release, stock, hatchery, etc., may prevent determining a direct relationship between survival and any one factor.

RESULTS AND DISCUSSION

Tagging of fall chinook for this project was completed in 1982. Fishery and hatchery sampling occurred in 1984 as planned.

Fishery Recoveries

Final estimated recoveries of tagged fall chinook are available for 1980 and 1981 from the Pacific Elarine Fisheries Commission for all U.S. Pacific coast fisheries except California in 1980 and California and Alaska in 1981. Final estimated recoveries for Canadian recoveries of salmon are available for 1980 through 1982 from the Department of Fisheries and Oceans. Preliminary estimated recoveries are available for 1982 from Oregon and Washington from State agency computer reports. Observed recoveries are available for all Pacific coast fisheries through 1983. Only preliminary observed recoveries are available for 1984.

Catches of 1978-brood fall chinook were expected to be completed in 1983. Catches of 1979-through 1981-brood fish could have occurred in 1984 (Table 5). Estimated recoveries of fall chinook tagged for this project are presented in Tables 7 through 9. Appendix Tables 1 through 4 contain the observed recoveries 'by brood year.

Hatchery Returns

Returns of tagged fall chinook through 1983 are summarized by brood, rearing facility and year of return in Tables 10 through 13. As with the catches, returns of the 1978-brood fall chinook were likely completed in 1983 and 1979 through 1981 broods could have returned in 1984. Appendix Tables 5 through 13 present the tag returns in more detail by brood, year of return, rearing facility and the site of return of the tagged fish. The total returns for 1980 through 1984 are listed in Table 14 by return facility. Appendix Tables 14 through 18 present the returns by return year, facility and sex.

Total fall chinook returns in 1983 for all facilities were the lowest of the five return years of the study (73,465). Despite this several hatcheries (Cowlitz, Elokomin, and Washougal) had the best returns of the five years in 1983.

Total returns in 1984 were slightly higher than in 1983 (74,401). Return numbers to Bonneville, Spring Creek, Little White Salmon, Klickitat and Klaskanine hatcheries were lower than any previous year during this study. Returns to Priest Rapids and Sea Resources; however, were greater than in the previous five years.

Comparisons of individual hatchery returns over the five years is complicated by several factors. The effects of openings and closings of commercial gillnet seasons in the Columbia River have differing influences on different hatcheries in the Columbia. Returns to hatcheries on small streams (Abernathy, Big Creek, Klaskanine, Elokimin, Grays River and Lower Kalama) are influenced by the date and quantity of the first fall rains. In general the earlier the beginning of the rains the larger the return to these facilities. Also some hatcheries are not efficient at capturing returning jack salmon, particularly those where salmon are trapped in the stream below the hatchery (Elokomin and Kalama Falls). Some of the jack salmon can swim through the bars of the traps.

Observations ,

Final estimated catch data is not yet available for any complete brood of fall chinook marked for this study. Values are available through 1982 for British Columbia, Washington, Oregon and Columbia River fisheries. Fall chinook from the Columbia River hatcheries are predominately recovered in these fisheries. The available catch data for Pacific coast fisheries are sufficient for making some interesting observations. Catches, returns and releases by rearing facility and tag code for the 1978 and 1979 broods of fall chinook are compared in Tables 15 and 16. The catch per 1,000 releases and percent survival figures are minimal for broods. The estimated catches in 1983 of 5-year-old marked fish from the 1978 brood are not available for inclusion in the catch. This is also the case for catches in 1983 and 1984 of 4-and 5-year-old fish from the 1979 brood. Also no adjustments in catches have been made for potential post release mortality of tagged fish. The percent survival values in Table 15 were calculated by summing the catches and returns and dividing by the releases.

A comparison of the catches of 1978 and 1979-brood fall chinook salmon from all hatcheries combined shows a higher contribution for the 1979 brood. This is in spite of the fact only two years of estimated catches are included in the catch per 1,000 releases figures for this brood versus three years for the 1978 brood. The percent catches by fishery are 40.3, 35.0, 7.5 and 17.2 for the Canadian, Washington, Oregon and Columbia River fisheries for the 1978-brood and 31.1, 42.9, 6.1 and 20.0 for the same fisheries respectively for the 1979 brood.

Fall chinook salmon from Spring Creek Hatchery are showing the best contributions to the fisheries. The catch per 1,000 release figures for Spring Creek, in most cases, far exceed the figures for other hatcheries. Spring Creek is followed in contribution by Stayton Pond, Abernathy, Big Creek and Bonneville. The descending order of the contribution rate of these hatcheries differs among the broods.

A preliminary comparison of contributions between 1978 and 1979 broods and among release dates at Spring Creek can be made using available estimated catches. From the 1978-brood estimated catches it appears about 85% of the Spring Creek fall chinook are caught as 2- and 3-year-old fish. The observed catches of 4-year-old fish from the 1979 brood do not indicate estimated recoveries of these fish in 1983 will increase the catches much more than 15%.

Releases of 1978- and 1979-brood fall chinook salmon occurred in March, April, May and August at Spring Creek. The releases of the 1979 brood occurred 6 to 10 days earlier than the 1978 brood in all cases (Tables 2 and 3). The sizes of releases were approximately the same for the same release months for both broods. Even without including 4-year-old catches of 1979-brood fish, the catches per 1,000 releases are higher fur the 1979 brood, for all but one of the release times, than the 1978 brood (Tables 15 and 16). When the 4-year-old catches are added to the April release of 1979-brood fish, it will likely be higher than the 1978-brood April release.

For the 1978 brood at Spring Creek, the April release has the largest contribution to the fisheries. For the 1979 brood, the May release has a slightly higher contribution than the April release. This could change when estimated catches for 1983 become available since there are 11 observed catches for the April release and 8 for the May release (Appendix Table 2). The May release of 1975 brood chinook occurred on the 9th prior to the Mt. St. Helens eruption. The Jones Beach smolt sampling operation, which is below the confluence of the Columbia and Cowlitz rivers, began capturing chinook from the May release, on May 12. Half of the fish captured at Jones Beach from this release had occurred by May 14, 1980. Thus it appears better than half the May release had migrated past Jones Beach prior to the eruption. The reasons for the higher contribution of the 1979-brood fish are not evident at this time.

There is considerable similarity between the catch per 1,000 releases for the 1978 and 1979 broods of fall chinook from Stayton Pond and Abernathy Hatchery. The values are 6.3 for the 1978 brood and 6.2 for the 1979 brood for Stayton Pond. For Abernathy Hatchery the values are 4.1 and 3.6 for the same broods respectively.

There is a dramatic difference between brood year contributions at Big Creek and Bonneville. The catch per 1,000 release values at Big Creek were 2.6 for the 1978 brood and 7.4 for the 1979 brood. Both broods were released at a similar size, 81 fish per pound and 78 fish per pond for the 1978 and 1979 broods respectively. The fish were also released about the same time of year May 21, 1979 for the 1978 brood and May 13, 1980 for the 1979 brood. Minor disease problems were recorded for the 1978-brood fish but no treatment was deemed necessary. No disease problems were recorded for the 1979 brood. Similar total numbers of fish were released both years, 5.2 and 6.4 million for the 1978 and 1979 broods respectively.

One difference between broods is the 1979-brood fish were released five days prior to the eruption of Mt. St. Helens in 1980. Six million fish could not have held in Big Creek and migrated when the Columbia River cleared. Thus the fish must have been in the Columbia River when the eruption occurred. One would speculate the turbid water in the Lower Columbia after the eruption would be a detriment to the health and survival of these fish. Thus one might expect the Big Creek fish to migrate into the clearer water of adjacent streams or be forced out to sea. From the examination of Appendix Tables 5 through 13, it can be seen returns of Big Creek fall chinook have a tendency to stray to adjacent streams. The magnitude of the straying does not appear to be different among the four broods released from the hatchery. It appears a majority of the fish were forced or quickly voluntarily migrated to sea.

Catches of Big Creek fish occurred in Canadian, Washington and Oregon marine and in the Columbia River fisheries. Increased catches of 1979-brood fish occurred in all of these fisheries as jacks and adults. The reason for the vast difference between the contribution of the two broods is not clear at this time.

At Bonneville Hatchery, the fall chinook are reared in two different water sources, constant temperature well water and fluctuating colder Tanner Creek water. The well water reared fish reach a 70 to 80 fish per pound release size 3 to 4 weeks before the creek water reared chinook. The well water reared fish are released in early May and the creek water fish in late May. The well and creek water reared fall chinook were both represented by the same tag code for the 1978 brood. Disease prevented tagging of the 1979-brood chinook reared in well water. Thus only the creek water reared fish were represented by a tag code.

The contribution per 1,000 releases for the 1978-brood fish from Bonneville Hatchery is over three times that of the 1979 brood. Observed catches of 1979-brood chinook do not appear to be extensive enough to make up much of the difference between the two contributions rates. The release of 1979-brood fish reared in creek water occurred after the eruption of Mt. St. Helens; May 20, 27 and 28, 1980. These fish had to migrate through the turbid water in the lower Columbia River. One could speculate the creek water reared chinook do not survive as well as well water reared fish and/or the migration of the 1979-brood fish through the turbid water of the Lower Columbia River had a significant negative impact on the survival of these fish.

The remainder of the hatcheries had catches per 1,000 release of 2 or less for both the 1978 and 1979 broods, except for two small releases at Cowlitz Hatchery. A 1978-brood release represented by code 63-19-51 contributed 6 fish per 1,000 releases and a 1979 brood represented by code 63-21-37 has so far contributed over 4 fish per 1,000 releases. Tag code 63-19-51 represented a small group from two ponds at the hatchery. Releases were made in late June and mid October in 1979. The October release fish were 19 per pound and made up 70% of the release. Tag code 63-21-37 represented a yearling release of fall chinook in March and April of 1981. These fish were about 10 fish per pound. It appears the larger fish had a higher survival than their smaller sub-yearling counter parts released in June of 1979 and 1980. Survival comparisons of the 1987- and 1979-brood fish at Cowlitz Hatchery are somewhat complicated by the eruption of Mt. St. Helens in 1980 and the transport of all the 1979-brood releases of sub-yearlings made in June and July to streams outside the Cowlitz system.

There is some indication from comparisons of the catches of the 1978 and 1979 broods that releases of fall chinook salmon under 100 fish per pond prior to June have a higher fishery contribution and survival than fish released smaller than 100 per pound and/or after the end of May. Fall releases of large fall chinook appear to have a better fishery contribution than early summer releases of fish in the 100 per pound size range. This trend will be examined further as estimated catch data become available for years after 1982.

Summary of Expenditures

Expenditures for this project in FY84 were approximately $29,500. They are itemized in Table 17.

Table 17.--Summary of Costs - FY 1984

Personnel Services and Benefits	$10,225.87
Travel and Transportation of Persons	184.96
Transportation of Things	0
SLUC	643.35
Contractual Services (USFWS)	15,100.00*
Total Direct Costs	$26,154.18
NOAA Support	3,252.62
DOC Support	71.55
TOTAL	$29,478.35

* U.S. Fish and Wildlife Service has not submitted a final voucher. When they do, this cost may diminish slightly, since it includes a small accrual.
